

Week 1 -Algorithms_DataStructures - Hands-On Exercises

Exercise 2: E-commerce Platform Search Function

1. Big O Notation:

Big-O Notation is a way to express the **upper bound** of an algorithm's time or space complexity.

- It provides a way to describe how the **runtime** or **space requirements** of an algorithm grow as the input size increases.
- Allows programmers to compare different algorithms and choose the most efficient one for a specific problem.
- Helps in understanding the scalability of algorithms and predicting how they will perform as the input size grows.
- Enables developers to optimize code and improve overall performance.

Best,Average and Worst cases:

**Best case is the function which performs the minimum number of steps on input data of n elements.*

**Worst case is the function which performs the maximum number of steps on input data of size n .*

**Average case is the function which performs an average number of steps on input data of n elements.*

2.CODE:

Java Files: Product.java, SearchDemo.java

Product.java

```
public class Product {  
  
    int productId;  
  
    String productName;
```

```
String category;
```

```
public Product(int id, String name, String category) {
```

```
    this.productId = id;
```

```
    this.productName = name;
```

```
    this.category = category;
```

```
}
```

```
public String toString() {
```

```
    return "ID: " + productId + ", Name: " + productName + ", Category: " + category;
```

```
}
```

```
}
```

SearchDemo.java

```
import java.util.Arrays;
```

```
import java.util.Comparator;
```

```
public class SearchDemo {
```

```
    public static Product linearSearch(Product[] products, String targetName) {
```

```
        for (Product product : products) {
```

```
            if (product.productName.equalsIgnoreCase(targetName)) {
```

```
                return product;
```

```
            }
```

```
        }
```

```
        return null;
```

```
}
```

```

public static Product binarySearch(Product[] products, String targetName) {

    int left = 0;

    int right = products.length - 1;

    while (left <= right) {

        int mid = (left + right) / 2;

        int cmp = products[mid].productName.compareToIgnoreCase(targetName);

        if (cmp == 0) return products[mid];

        else if (cmp < 0) left = mid + 1;

        else right = mid - 1;

    }

    return null;

}

public static void main(String[] args) {

    Product[] products = {

        new Product(1, "Laptop", "Electronics"),

        new Product(2, "Shoes", "Footwear"),

        new Product(3, "Watch", "Accessories"),

        new Product(4, "Phone", "Electronics"),

        new Product(5, "T-Shirt", "Apparel")

    };

    System.out.println("Linear Search for 'Watch':");

    Product result1 = linearSearch(products, "Watch");

    System.out.println(result1 != null ? result1 : "Product not found");

    Arrays.sort(products, Comparator.comparing(p ->
p.productName.toLowerCase()));

```

```

        System.out.println("\nBinary Search for 'Watch':");

        Product result2 = binarySearch(products, "Watch");

        System.out.println(result2 != null ? result2 : "Product not found");

    }

}

```

OUTPUT:

The screenshot shows an IDE with a Java file named `SearchDemo.java`. The code defines a `SearchDemo` class with two methods: `linearSearch` and `binarySearch`. The `linearSearch` method prints the result of a linear search for 'Watch', and the `binarySearch` method prints the result of a binary search for 'Watch'. The output window shows the execution of the program, displaying the results of both searches.

```

PS C:\Users\samin\EcommerceSearchExample> & 'C:\Program Files\Java\jdk-17\bin\java.exe' '-XX:+ShowCodeDetailsInExceptionMessages' '-cp' 'C:\Users\samin\AppData\Roaming\Code\User\workspaceStorage\9f2eb2225d96f2e3e9e2218fc7c3479a\redhat.java\jdt_ws\EcommerceSearchExample_12c1e18c\bin' 'SearchDemo'
Linear Search for 'Watch':
ID: 3, Name: Watch, Category: Accessories

Binary Search for 'Watch':
ID: 3, Name: Watch, Category: Accessories
PS C:\Users\samin\EcommerceSearchExample>

```

3.ANALYSIS:

Time complexity:

Algorithm	Time complexity
Binary Search	$O(n)$
Linear Search	$O(\log n)$

=>Binary search is better for this platform because it's faster than linear search when the product list is sorted.

Exercise 7: Financial Forecasting

Recursion:

→ *Recursion is when a function calls itself to solve a smaller part of the problem.*

→ *It simplifies code for problems like repeated calculations.*

CODE:

Java Files: Forecast.java, Main.java

Forecast.java

```
public class Forecast {  
  
    public static double futureValueRecursive(double presentValue, double rate, int  
years) {  
  
        if (years == 0) {  
  
            return presentValue;  
  
        }  
  
        return futureValueRecursive(presentValue, rate, years - 1) * (1 + rate);  
  
    }  
  
}
```

Main.java

```
public class Main {  
  
    public static void main(String[] args) {  
  
        double presentValue = 1000;  
  
        double rate = 0.05;
```

```

int years = 10;

System.out.println("Financial Forecast using Recursion:");

double future = Forecast.futureValueRecursive(presentValue, rate, years);

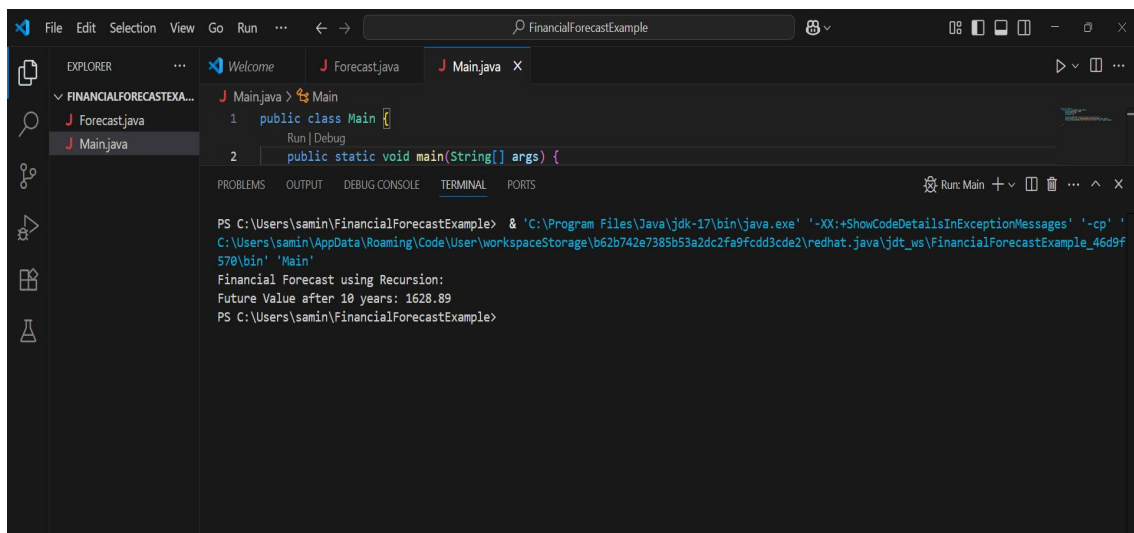

System.out.printf("Future Value after %d years: %.2f%n", years, future);

}

}

```

OUTPUT:

```

PS C:\Users\samin\FinancialForecastExample> & 'C:\Program Files\Java\jdk-17\bin\java.exe' '-XX:+ShowCodeDetailsInExceptionMessages' '-cp' 'C:\Users\samin\AppData\Roaming\Code\User\workspaceStorage\b62b742e7385b53a2dc2fa9fcd3cde2\redhat_java\jdt_ws\FinancialForecastExample_46d9f570\bin' 'Main'
Financial Forecast using Recursion:
Future Value after 10 years: 1628.89
PS C:\Users\samin\FinancialForecastExample>

```

3.ANALYSIS:

>> Time complexity:

Recursive version- $O(n)$
